- Single Power Supply 5 V  $\pm$  10%
- Organization . . . 131 072 by 8 Bits
- Eight Equal Sectors of 16K Bytes
  - Any Combination of Sectors Can Be Erased
  - Any Combination of Sectors Can Be Marked as Read-Only
- Compatible With JEDEC EEPROM Command Set
- Fully Automated On-Chip Erase and Byte-Program Operations
- 100000 Program/Erase Cycles
- Compatible With JEDEC Byte-Wide Pinouts
- Low-Current Consumption
  - Active Read . . . 20 mA Typical
  - Active Program/Erase . . . 30 mA Typical
- All Inputs/Outputs TTL-Compatible

## description

The TMS29F010 is a 131072 by 8-bit (1048576-bit), 5-V single-supply, programmable read-only memory device that can be electrically erased and reprogrammed. This device is organized as eight independent 16K-byte sectors and is offered with access times between 70 ns and 120 ns.

No Connection

An on-chip state machine controls the program and erase operations. The embedded byte-program and sector/chip-erase functions are fully automatic. The command set is compatible with that of JEDEC 1M-bit EEPROMs. Data-protection of any sector combination is accomplished using a hardware sector-protection feature.

NC

Device operations are selected by writing JEDEC-standard commands into the command register using standard microprocessor write timings. The command register acts as an input to an internal-state machine that interprets the commands, controls the erase and programming operations, outputs the status of the device, outputs data stored in the device, and outputs the device algorithm-selection code. On initial power-up operation, the device defaults to the read mode.

The TMS29F010 is offered in a 32-pin plastic leaded chip carrier (FM suffix) using 1.27-mm (50-mil) lead pitch.

Please be aware that an important notice concerning availability, standard warranty, and use in critical applications of Texas Instruments semiconductor products and disclaimers thereto appears at the end of this data sheet.

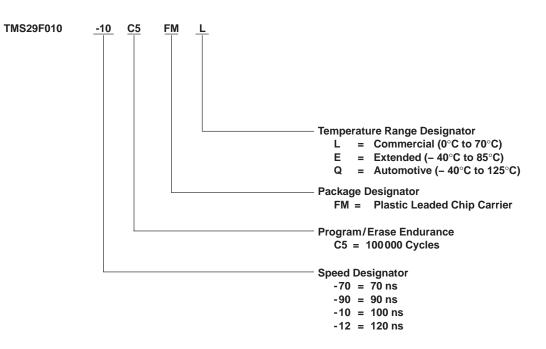

PRODUCTION DATA information is current as of publication date. Products conform to specifications per the terms of Texas Instruments standard warranty. Production processing does not necessarily include testing of all parameters.

Table 1. Operation Modes

<sup>†</sup> X can be V<sub>IL</sub> or V<sub>IH</sub>.

<sup>‡</sup> See Table 3 for valid address and data during write (byte program).

§ Operation at V<sub>CC</sub> = 5.0 V and T<sub>A</sub> = 25°C.

NOTES: 1. Address pins A7, A12 =  $V_{IH}$ .

2. See Figure 6 through Figure 9.

#### read mode

To read the output of the TMS29F010, a low-level logic signal is applied to the  $\overline{E}$  and  $\overline{G}$  pins. When two or more TMS29F010 devices are connected in parallel, the output of any one device can be read without interference. The  $\overline{E}$  pin is power control and is used for device selection. The  $\overline{G}$  pin is output control and is used to gate the data output onto the bus from the selected device.

The address-access time ( $t_{AVQV}$ ) is the delay from stable address to valid output data. The chip-enable access time ( $t_{ELQV}$ ) is the delay from  $\overline{E} = V_{IL}$  and stable addresses to valid output data. The output-enable access time ( $t_{GLQV}$ ) is the delay from  $\overline{G} = V_{IL}$  to valid output data when  $\overline{E} = V_{IL}$  and addresses are stable for at least the duration of  $t_{AVQV} - t_{GLQV}$ .

## standby mode

The I<sub>CC</sub> supply current is reduced by applying a logic-high level on  $\overline{E}$  to enter the standby mode. In the standby mode, the outputs are placed in the high-impedance state. Applying a CMOS logic-high level on  $\overline{E}$  reduces the current to 100  $\mu$ A maximum. Applying a TTL logic-high level on  $\overline{E}$  reduces the current to 1 mA maximum.

If the TMS29F010 is deselected during erasure or programming, the device continues to draw active current until the operation is complete.

## output disable

When either  $\overline{G} = V_{IH}$  or  $\overline{E} = V_{IH}$ , output from the device is disabled and the output pins (DQ0-DQ7) are placed in the high-impedance state.

## algorithm-selection mode

The algorithm-selection mode provides access to a binary code that matches the device with its proper programming- and erase-command operations. This mode is activated when  $V_{ID}$  (11.5 V to 12.5 V) is placed on address pin A9. Address pin A1 must be logic-low. Two bytes of code are accessed by toggling address pin A0 from  $V_{II}$  to  $V_{IH}$ . All other address pins can be logic-low or logic-high.

The algorithm-selection code can also be read by using the command register. This is useful when  $V_{\text{ID}}$  is not available to be placed on address pin A9. Table 2 shows the binary algorithm-selection codes for the TMS29F010.

ALGORITHM SELECTION	A0	DQ7	DQ6	DQ5	DQ4	DQ3	DQ2	DQ1	DQ0	HEX
Byte 0	0	0	0	0	0	0	0	0	1	01h
Byte 1	1	0	0	1	0	0	0	0	0	20h
$†$ A1 = V <sub>IL</sub> , $\overline{E} = \overline{G} = V_{IL}$										

## Table 2. Algorithm-Selection Codes<sup>†</sup>

erasure and programming

Erasure and programming of the TMS29F010 are accomplished by writing a sequence of commands using standard microprocessor-write timings. The commands are written to a command register and input to the command-state machine (CSM). The CSM interprets the command entered and initiates program and erase operations as instructed. The CSM acts as the interface between the write-state machine (WSM) and the external chip operations. The WSM controls all voltage generation, pulse generation, preconditioning, and verification of the memory contents. Program and sector/chip-erase functions are fully automatic. Once the end of a program or erase operation is reached, the device internally resets to the read mode. If  $V_{CC}$  drops below the low-voltage-detect level ( $V_{LKO}$ ), any operation in progress is aborted and the device resets to the read mode. If a byte-program or chip-erase operation is in progress, additional program/erase commands are ignored until the operation ends.

## command definitions

Device operating modes are selected by writing specific address and data sequences into the command register. Table 3 defines the valid command sequences. Writing incorrect address and data values or writing them in the incorrect sequence causes the device to reset to the read mode. The command register does not occupy an addressable memory location. The register stores the command sequence, along with the address and data needed by the memory array. Commands are written by setting  $\overline{E} = V_{IL}$  and  $\overline{G} = V_{IH}$ , and bringing  $\overline{W}$  from  $V_{IH}$  to  $V_{IL}$ . Addresses are latched on the falling edge of  $\overline{W}$  and data is latched on the rising edge of  $\overline{W}$ . Holding  $\overline{W} = V_{IL}$  and toggling  $\overline{E}$  is an alternative method. See the byte-program and chip/sector-erase sections for a more complete description.

## command definitions (continued)

COMMAND	BUS CYCLES	1ST CYCLE ADDR DATA	2ND CYCLE ADDR DATA	3RD CYCLE ADDR DATA	4TH CYCLE ADDR DATA	5TH CYCLE ADDR DATA	6TH CYCLE ADDR DATA
Read <sup>‡</sup>	1	RA RD					
Decest/Decest&	2	XXXXh F0h	RA RD				
Reset/Read§	4	5555h AAh	2AAAh 55h	5555h F0h	RA RD		
Algorithm selection	4	5555h AAh	2AAAh 55h	5555h 90h	RA RD		
Byte program	4	5555h AAh	2AAAh 55h	5555h A0h	PA PD		
Chip erase	6	5555h AAh	2AAAh 55h	5555h 80h	5555h AAh	2AAAh 55h	5555h 10h
Sector erase	6	5555h AAh	2AAAh 55h	5555h 80h	5555h AAh	2AAAh 55h	SA 30h

## Table 3. Command Definitions<sup>†</sup>

RA = Address of the location to be read

PA = Address of the location to be programmed

SA = Address of the sector to be erased

Addresses A14, A15, and A16 select one of eight sectors

RD = Data to be read at the selected address location

PD = Data to be programmed at the selected address location

<sup>†</sup> Address pins A15 and A16 = V<sub>IL</sub> or V<sub>IH</sub> for all bus-cycle addresses except for program address (PA), sector address (SA), and read address (RA).

<sup>‡</sup>No command cycles are required when the device is in read mode.

§ The reset command is required to return to the read mode when the device is in the algorithm-selection mode or if DQ5 goes high.

#### reset/read command

The read mode is activated by writing either of the two reset command sequences into the command register. The device remains in this mode until another valid command sequence is input into the command register. Memory data is available in the read mode and can be read with standard microprocessor read-cycle timing.

On power up, the device defaults to the read mode; therefore, a reset command sequence is not required and memory data is available.

#### algorithm-selection command

The algorithm-selection command allows access to a binary code that matches the device with the proper programming- and erase-command operations. After writing the three-bus-cycle command sequence, the first byte of the algorithm-selection code (01h) can be read from address XX00h. The second byte of the code (20h) can be read from address XX01h (see Table 2). This mode remains in effect until another valid command sequence is written to the device.

Sector protection can be determined by using the algorithm-selection command. After issuing the three bus-cycle command sequence, the sector-protection status can be read on DQ0. Set address pins A0 =  $V_{IL}$  and A1 =  $V_{IH}$ , and then the sector address pins A14, A15, and A16 select the sector to be checked. The remaining address pins can be  $V_{IL}$  or  $V_{IH}$ . If the sector that is selected is protected, DQ0 outputs a 1 state, and, if the sector selected is not protected, DQ0 outputs a 0 state. This mode remains in effect until another valid command sequence is written to the device.

## byte-program command

Byte programming is a four-bus-cycle command sequence. The first three bus cycles put the device into the program-setup state, and the fourth bus cycle loads the address location and the data to be programmed into the device. The addresses are latched on the falling edge of  $\overline{W}$  and the data is latched on the rising edge of  $\overline{W}$  in the fourth bus cycle. The rising edge of  $\overline{W}$  starts the byte-program operation. The embedded byte-programming function automatically provides needed voltage and timing to program and to verify the cell margin. Any further commands written to the device during the program operation are ignored.

## byte-program command (continued)

Programming can be performed at any address location in any order, resulting in logic 0s being programmed into the device. Attempting to program a logic 1 into a bit that has been previously programmed to a logic 0 causes the internal pulse counter to exceed the pulse-count limit. This sets the exceed-timing-limit indicator (DQ5) to a logic-high state. Only an erase operation can change bits from logic 0s to logic 1s. When erased, all bits become logic 1. Figure 3 shows a flow chart of the typical byte-programming operation.

The status of the device during the automatic programming operation can be monitored for completion using the data-polling feature or the toggle-bit feature. See the operation-status section for a full description.

#### chip-erase command

Chip erase is a six-bus-cycle command sequence. The first three bus cycles put the device into the erase-setup state, and the next two bus cycles unlock the erase mode. The sixth bus cycle loads the chip-erase command. This command sequence is required to ensure that the memory contents are not erased accidentally. The rising edge of  $\overline{W}$  starts the chip-erase operation. Any further commands written to the device during the chip-erase operation are ignored.

The embedded chip-erase function automatically provides voltage and timing needed to program and verify all the memory cells prior to electrical erase and then erases and verifies the cell margin automatically. The user is not required to program the memory cells prior to erase. The status of the device during the automatic chip-erase operation can be monitored for completion using the data-polling feature or the toggle-bit feature. See the operation status section for a full description. Figure 6 shows a flow chart for the typical chip-erase operation.

#### sector-erase command

Sector erase is a six-bus-cycle command sequence. The first three bus cycles cause the device to go into the erase-setup state, and the next two bus cycles unlock the erase mode. The sixth bus cycle loads the sector-erase command and the sector-address location to be erased. Any address location within the desired sector can be used. The addresses are latched on the falling edge of  $\overline{W}$  and the sector-erase command (30h) is latched on the rising edge of  $\overline{W}$  in the sixth bus cycle. After a delay of 80 µs from the rising edge of  $\overline{W}$ , the sector-erase operation begins on the selected sector(s).

Additional sectors can be selected to be erased concurrently during the sector-erase command sequence. For each additional sector selected for erase, another bus cycle is issued. The bus cycle loads the next sector-address location and the sector-erase command. The time between the end of the previous bus cycle and the start of the next bus cycle must be less than 80  $\mu$ s—otherwise, the new sector location is not loaded. A time delay of 80  $\mu$ s from the rising edge of the last  $\overline{W}$  cycle starts the sector-erase operation. If there is a falling edge of  $\overline{W}$  within the 80- $\mu$ s time delay, the timer is reset.

One to eight sector-address locations can be loaded in any order. The state of the delay timer can be monitored using the sector-erase-delay indicator (DQ3). If DQ3 is logic low, the time delay has not expired. See the operation-status section for a full description.

Any command other than sector-erase (30h) written to the device during the sector-erase operation causes the device to exit the sector-erase mode; meanwhile, the contents of the sector(s) selected for erase are no longer valid. To complete the sector-erase operation, the sector-erase command sequence must be repeated.

The embedded sector-erase function automatically provides needed voltage and timing to program and to verify all of the memory cells prior to electrical erase and then erases and verifies the cell margin automatically. Programming the memory cells prior to erase is not required. The status of the device during the automatic sector-erase operation can be monitored for completion by using the data-polling feature or the toggle-bit feature. See the operation-status section for a full description. Figure 8 shows a flow chart of the typical sector-erase operation.

## operation status

## status bit definitions

During operation of the embedded program and erase functions, the status of the device can be determined by reading the data state of designated outputs. The data-polling bit (DQ7) and toggle-bit (DQ6) require multiple successive reads to observe a change in the state of the designated output. Table 4 defines the values of the status flags.

Device Operation <sup>‡</sup>	DQ7	DQ6	DQ5	DQ4	DQ3	DQ2	DQ1	DQ0
Byte-programming in progress	DQ7	Т	0	Х	0	Х	Х	Х
Byte-programming exceed time limit	DQ7	Т	1	Х	0	Х	Х	Х
Byte-programming complete	D	D	D	D	D	D	D	D
Sector/chip-erase in progress	0	Т	0	Х	1	Х	Х	Х
Sector/chip-erase exceed time limit	0	Т	1	Х	1	Х	Х	Х
Sector/chip-erase complete	1	1	1	1	1	1	1	1

## Table 4. Operation Status Flags<sup>†</sup>

<sup>†</sup>T= toggle, D = data, X = data undefined,  $\overline{DQ7}$  = complement of data written to DQ7

<sup>‡</sup>DQ4, DQ2, DQ1, DQ0 are reserved for future use.

## data-polling (DQ7)

The data-polling status function outputs the complement of the data latched into the DQ7 data register while the write-state machine (WSM) is engaged in a program or erase operation. Data bit DQ7 changes from complement to true to indicate the end of an operation. Data polling is available only during the byte-programming, chip-erase, sector-erase, and sector-erase timing delay. Data polling is valid after the rising edge of W in the last bus cycle of the command sequence loaded into the command register. Figure 10 shows a flow chart of the data-polling operation.

During a byte-program operation, reading DQ7 outputs the complement of the DQ7 data to be programmed at the selected address location. Upon completion, reading DQ7 outputs the true DQ7 data loaded into the program data register. During erase operations, reading DQ7 outputs a logic 0, and upon completion, reading DQ7 outputs a logic 1. Also, data polling must be performed at a sector address that is within a sector being erased; otherwise, the status is not valid. When using data polling, the address must remain stable throughout the operation.

During a data-polling read, while  $\overline{G}$  is low, DQ7 can change asynchronously with the other DQs. Depending on the read timing, the system can read valid data on DQ7, while other DQ pins are still invalid. The data on DQ0–DQ7 is valid with a subsequent read of the device. See Figure 11 for the data-polling timing diagram.

## toggle-bit (DQ6)

The toggle-bit status function outputs data on DQ6 that toggles between logic 1 and logic 0 while the WSM is engaged in a program or erase operation. When toggle-bit DQ6 stops toggling after two consecutive reads to the same address, the operation is complete. The toggle bit is available only during the byte-programming, chip-erase, sector-erase, and sector-erase timing delay. Toggle bit data is valid after the rising edge of  $\overline{W}$  in the last bus cycle of the command sequence loaded into the command register. Figure 12 shows a flow chart for the toggle-bit status-read algorithm. Depending on the read timing, DQ6 can stop toggling while other DQ pins are still invalid. The data on DQ0–DQ7 is valid with a subsequent read of the device. Figure 13 shows the toggle-bit timing diagram.

## exceed-time-limit (DQ5)

The program and erase operations use an internal pulse counter to limit the number of pulses applied. If the pulse count limit is exceeded, DQ5 is set to a logic 1, indicating that the program or erase operation has failed. DQ7 will not change from complemented data to true data and DQ6 will not stop toggling when read. To continue operation, the device must be reset.

The exceed-time-limit condition occurs when attempting to program a logic 1 into a bit that has been programmed previously to a logic 0. Only an erase operation can change bits from logic 0 to logic 1. After reset, the device is functional and can be erased and reprogrammed.

## sector-load-timer (DQ3)

The sector-load-timer status bit, DQ3, is used to determine if the time to load additional sector addresses has expired. After completion of a sector-erase command sequence, DQ3 remains at a logic 0 for 80  $\mu$ s. This indicates that another sector-erase command sequence can be issued. DQ3 set at a logic 1 indicates that the delay has expired and attempts to issue additional sector-erase commands are ignored. See the sector-erase command sector-erase command sector-erase commands are ignored. See the sector-erase command sector-erase command sector-erase commands are ignored.

The data-polling bit and toggle bit are valid during the 80-µs time delay and can be used to determine if a valid sector-erase command has been issued. To ensure additional sector-erase commands have been accepted, the status of DQ3 should be read before and after each additional sector-erase command. If DQ3 is at a logic low on both reads, then the additional sector-erase command was accepted.

## data protection

### hardware-sector protect feature

This feature disables both programming and erase operations on any combination of one to eight sectors. Commands to program or erase a protected sector do not change the data contained in the sector. The data-polling and toggle bits operate for 2  $\mu$ s to 100  $\mu$ s and then return to valid data. This feature is enabled using high-voltage V<sub>ID</sub> (11.5 V to 12.5 V) on address pin A9 and control pin  $\overline{G}$ , and V<sub>IL</sub> on control pin  $\overline{E}$ . Figure 14 shows a flow chart of the sector-protect operation.

The device is delivered with all sectors unprotected; however, sector-unprotect mode is available to unprotect protected sectors. Figure 16 is a flow chart of the sector-unprotect operation.

## sector-protect operation

The sector-protect mode is activated when  $V_{CC} = 5.0 \text{ V}$  (and operation at  $T_A = 25^{\circ}\text{C}$ ),  $\overline{W} = V_{IH}$ ,  $\overline{E} = V_{IL}$ , and address pin A9 and control pin  $\overline{G}$  are forced to  $V_{ID}$ . The sector-select address pins A14, A15, and A16 are used to select the sector to be protected. Address pins A0–A8, A10–A13, and I/O pins DQ0–DQ7 must be stable and can be  $V_{IL}$  or  $V_{IH}$ . Once the addresses are stable,  $\overline{W}$  is pulsed low for 100 µs. The operation begins on the falling edge of  $\overline{W}$  and terminates on the rising edge of  $\overline{W}$ . Figure 15 shows a timing diagram of the sector-protect operation.

## sector-protect verify

Verification of sector protection is activated when  $V_{CC} = 5.0 \text{ V}$  (and operation at  $T_A = 25^{\circ}\text{C}$ ),  $\overline{W} = V_{IH}$ ,  $\overline{G} = V_{IL}$ ,  $\overline{E} = V_{IL}$ , and address pin A9 =  $V_{ID}$ . Address pins A0 and A6 are set to  $V_{IL}$ , and A1 is set to  $V_{IH}$ . The sector-address pins A14, A15, and A16 select the sector to be verified. The other address pins can be  $V_{IL}$  or  $V_{IH}$ . If the sector selected is protected, the DQs output 01h, and if the sector selected is not protected, the DQs output 00h.

## sector unprotect operation

Prior to the sector-unprotect operation, all sectors should be protected using the sector-protect mode. Sector unprotect is activated when  $V_{CC} = 5.0 \text{ V}$  (and operation at  $T_A = 25^{\circ}\text{C}$ ),  $\overline{W} = V_{IH}$ , and address pin A9 and control pins  $\overline{G}$  and  $\overline{E}$  are forced to  $V_{ID}$ . Address pin A6 =  $V_{IL}$ , and pins A7 and A12 are set to  $V_{IH}$ . The sector-select address pins A14, A15, and A16 can be  $V_{IL}$  or  $V_{IH}$ . All eight sectors are unprotected in parallel, and once the inputs are stable,  $\overline{W}$  is pulsed low for 10 ms. The unprotect operation begins on the falling edge of  $\overline{W}$  and terminates on the rising edge of  $\overline{W}$ . Figure 17 shows a timing diagram of the sector-unprotect operation.

### sector-unprotect verify

Verification of sector-unprotect is accomplished when  $V_{CC} = 5.0 \text{ V}$  (and operation at  $T_A = 25^{\circ}C$ ),  $\overline{W} = V_{IH}$ ,  $\overline{G} = V_{IL}$ ,  $\overline{E} = V_{IL}$ , and address pin A9 =  $V_{ID}$ , and then select the sector to be verified. Address pins A1 and A6 are set to  $V_{IH}$  while pin A0 is set to  $V_{IL}$ . The other address pins can be  $V_{IH}$  or  $V_{IL}$ . If the sector that is selected is protected, the DQs output 01h and if the sector is not protected, the DQs output 00h.

## low V<sub>CC</sub> write lockout

During power up and power down, write operations are locked out for  $V_{CC}$  less than  $V_{LKO}$ . If  $V_{CC} < V_{LKO}$ , the command input is disabled and the device is reset to the read mode. On power up, if  $\overline{E} = V_{IL}$ ,  $\overline{W} = V_{IL}$ , and  $\overline{G} = V_{IH}$ , the device does not accept commands on the rising edge of  $\overline{W}$ . The device automatically powers up in the read mode.

## glitching

Pulses of less than 5 ns (typical) on  $\overline{G}$ ,  $\overline{W}$ , or  $\overline{E}$  do not issue a write cycle.

## power supply considerations

Each device should have a 0.1- $\mu$ F ceramic capacitor connected between V<sub>CC</sub> and V<sub>SS</sub> to suppress circuit noise. Printed circuit traces to V<sub>CC</sub> should be appropriate to handle the current demand and minimize inductance.

## absolute maximum ratings over operating ambient temperature range (unless otherwise noted)<sup>†</sup>

Voltage range	e with respect to ground:	
	Supply voltage range, V <sub>CC</sub> (see Note 3)	–2.0 V to + 7.0 V
	All pins except A9, E, G (see Note 3)	–2.0 V to + 7.0 V
	A9, E, G (see Note 4)	–2.0 V to + 14.0 V
Ambient temp	perature range during read/erase/program, T <sub>A</sub>	
	Commercial (L)	0°C to 70°C
	Extended (E)	–40°C to 85°C
	Automotive (Q)	–40°C to 125°C
Storage temp	perature range, T <sub>stg</sub>	–65°C to 150°C
	Commercial (L) Extended (E) Automotive (Q)	40°C to 85°C

<sup>†</sup> Stresses beyond those listed under "absolute maximum ratings" may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated under "recommended operating conditions" is not implied. Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability.

NOTES: 3. Minimum dc voltage on input or I/O pins is –0.5 V. During voltage transitions, input or I/O pins may undershoot V<sub>SS</sub> to –2.0 V for periods of up to 20 ns. Maximum dc voltage on input and I/O pins is V<sub>CC</sub> + 0.5 V. During voltage transitions, input and I/O pins may overshoot to V<sub>CC</sub> + 2.0 V for periods up to 20 ns.

Minimum dc input voltage on A9, Ē, and G pins is -0.5 V. During voltage transitions, A9, Ē, and G may undershoot V<sub>SS</sub> to -2.0 V for periods of up to 20 ns. Maximum dc input voltage on A9, Ē, and G pins is +12.5 V, which may overshoot to +14.0 V for periods up to 20 ns.

## recommended operating conditions

			MIN	NOM	MAX	UNIT
VCC	Supply voltage		4.5	5	5.5	V
		Commercial (L)	0		70	
Т <sub>А</sub>	Ambient temperature during read/erase/program	Extended (E)	-40		85	°C
		Automotive (Q)	-40		125

PARAMETER MEASUREMENT INFORMATION

- B. The ac testing inputs for -70 voltage waveforms are driven at 3 V for logic high and 0 V for logic low. Timing measurements for -70 voltage waveforms are made at 1.5 V for logic high and 1.5 V for logic low on both inputs and outputs. The ac testing inputs for -90, -10, and -12 voltage waveforms are driven at 2.4 V for logic high and 0.45 V for logic low. Timing measurements for -90, -10, and -12 voltage waveforms are made at 2 V for logic high and 0.8 V for logic low on both inputs and outputs.
- C. Each device should have a 0.1-µF ceramic capacitor connected between V<sub>CC</sub> and V<sub>SS</sub>, as closely as possible to the device pins.

### **IMPORTANT NOTICE**

Texas Instruments Incorporated and its subsidiaries (TI) reserve the right to make corrections, modifications, enhancements, improvements, and other changes to its products and services at any time and to discontinue any product or service without notice. Customers should obtain the latest relevant information before placing orders and should verify that such information is current and complete. All products are sold subject to TI's terms and conditions of sale supplied at the time of order acknowledgment.

TI warrants performance of its hardware products to the specifications applicable at the time of sale in accordance with TI's standard warranty. Testing and other quality control techniques are used to the extent TI deems necessary to support this warranty. Except where mandated by government requirements, testing of all parameters of each product is not necessarily performed.

TI assumes no liability for applications assistance or customer product design. Customers are responsible for their products and applications using TI components. To minimize the risks associated with customer products and applications, customers should provide adequate design and operating safeguards.

TI does not warrant or represent that any license, either express or implied, is granted under any TI patent right, copyright, mask work right, or other TI intellectual property right relating to any combination, machine, or process in which TI products or services are used. Information published by TI regarding third-party products or services does not constitute a license from TI to use such products or services or a warranty or endorsement thereof. Use of such information may require a license from a third party under the patents or other intellectual property of the third party, or a license from TI under the patents or other intellectual property of TI.

Reproduction of TI information in TI data books or data sheets is permissible only if reproduction is without alteration and is accompanied by all associated warranties, conditions, limitations, and notices. Reproduction of this information with alteration is an unfair and deceptive business practice. TI is not responsible or liable for such altered documentation. Information of third parties may be subject to additional restrictions.

Resale of TI products or services with statements different from or beyond the parameters stated by TI for that product or service voids all express and any implied warranties for the associated TI product or service and is an unfair and deceptive business practice. TI is not responsible or liable for any such statements.

TI products are not authorized for use in safety-critical applications (such as life support) where a failure of the TI product would reasonably be expected to cause severe personal injury or death, unless officers of the parties have executed an agreement specifically governing such use. Buyers represent that they have all necessary expertise in the safety and regulatory ramifications of their applications, and acknowledge and agree that they are solely responsible for all legal, regulatory and safety-related requirements concerning their products and any use of TI products in such safety-critical applications, notwithstanding any applications-related information or support that may be provided by TI. Further, Buyers must fully indemnify TI and its representatives against any damages arising out of the use of TI products in such safety-critical applications.

TI products are neither designed nor intended for use in military/aerospace applications or environments unless the TI products are specifically designated by TI as military-grade or "enhanced plastic." Only products designated by TI as military-grade meet military specifications. Buyers acknowledge and agree that any such use of TI products which TI has not designated as military-grade is solely at the Buyer's risk, and that they are solely responsible for compliance with all legal and regulatory requirements in connection with such use.

TI products are neither designed nor intended for use in automotive applications or environments unless the specific TI products are designated by TI as compliant with ISO/TS 16949 requirements. Buyers acknowledge and agree that, if they use any non-designated products in automotive applications, TI will not be responsible for any failure to meet such requirements.
